6 Abstract

Background: Cash transfer programs have the potential to improve dietary intake by
improving accessibility to food. However, quantitative data on the impact of cash transfer
programs on children's energy and nutrient intake is lacking.

Objective: The aim of this study was to evaluate the effect of seasonal unconditional cash
 transfer on children's energy, micro and macronutrient and food group intake during the lean
 season in Burkina Faso.

Methods: Within the framework of the MAM'Out study, a cluster randomized controlled trial,
two 24-h dietary recall surveys were conducted in July and August 2014. Daily energy,
macro- and micronutrient intake, breastfeeding practices, as well as food group consumption,

were analyzed for 322 children aged 14 to 27 months from the intervention group (benefiting
from unconditional cash transfer during the lean season 2013 and 2014) and the control
group, using mixed linear/logistic/Poisson regression models or a gamma-generalized linear

19 model with log-link. A dietary diversity score was calculated based on seven food groups.

20 **Results**: Unconditional cash transfers during the lean season improved the diets of rural

children through higher consumption of eggs (11.3 g \pm 1.55 vs 3.25 g \pm 0.79, p<0.001), fat

22 $(20.6 \text{ g} \pm 0.80 \text{ vs} 16.5 \text{ g} \pm 0.89, \text{ p} < 0.01)$ and vitamin B12 $(0.40 \text{ mg} \pm 0.02 \text{ vs} 0.34 \text{ mg} \pm 0.02,$

p<0.001) compared to controls, and higher proportions of children eating dairy products (OR:

4.14 (1.48, 11.6), p<0.05), flesh food (OR: 2.09 (1.18, 3.70), p<0.05), eggs (OR: 3.61 (1.56,

25 8.37), p<0.05) and iron rich or iron fortified food (OR: 2.23 (1.20, 4.13), p<0.05). No

26 difference was found in energy intake between the two groups. The minimum dietary

27 diversity of two thirds of the children who benefited from cash transfers was adequate

compared to that of only one third in the control group (p<0.001).

Conclusion: Unconditional seasonal cash transfer increases dietary diversity and intake of
 high nutritional value foods in Burkinabe children aged 14 to 27 months. As such, their use

31 can be recommended in actions addressing children's dietary intake during the lean season.

32 Study registered in ClinicalTrials.gov (NCT01866124).

37 Introduction

38 Although progress has been made in the fight against child undernutrition in recent years, it 39 is still a public health issue worldwide [1]. Nutritional disorders, including wasting, stunting, vitamin A and zinc deficiencies, fetal growth restriction and inadequate breastfeeding are 40 responsible for 45% of all deaths among children under 5 years old, or 3.1 million deaths 41 annually [2]. In Burkina Faso, West Africa, child nutritional status is particularly worrying: 42 43 32.9% of all children under 5 are stunted, 10.9% wasted and 14% suffered from low birth weight in 2013 [3]. A recent study in rural Burkina Faso using biomarkers also found high 44 45 deficiency rates for zinc (25.6–73.5%) and moderate deficiency rates for vitamin A (6.0– 30.6%), as well as high rates of anemia (29.4–72.3%) among women and preschool children 46 47 [4].

To date, various strategies have been implemented in humanitarian contexts to tackle 48 49 children's undernutrition, including nutrition specific interventions such as food based 50 strategies [5-8] to address its direct causes, and nutrition sensitive activities to address its underlying determinants [9]. Among nutrition sensitive activities, social safety nets, mainly 51 implemented as cash transfer programs, have been shown to have positive effects on food 52 security [10-12] and on household expenditures on food [13, 14]. However, most studies that 53 54 have evaluated the impact of cash transfer on child nutritional status used proxies such as dietary diversity scores [12, 15, 16] that do not enable assessment of whether energy and 55

nutrient intake in the child's diet are adequate. There is thus a lack of quantitative data on the
effect of cash transfer programs on children's dietary intake.

A multiannual seasonal and unconditional cash transfer program was implemented in 2013 58 59 and 2014 in Tapoa Province, in the Eastern Region of Burkina Faso, in the framework of the MAM'Out study. We designed a cluster randomized controlled trial to evaluate the effect of 60 61 the program on the prevention of child acute malnutrition [17]. The main objective of this 24-h dietary recall sub-study was to assess the impact of the cash transfer program in the first 62 place on the energy intake of beneficiary children aged between 14 and 27 months during 63 the 2014 annual lean season, corresponding to the period between harvests May to 64 65 September when people rely on market for their food needs. We further compared the micro-66 and macronutrient intakes between intervention and control groups.

67

68 Methods

69 The MAM'Out study

70 The Moderate Acute Malnutrition Out (MAM'Out) study [17] was implemented from June 71 2013 to October 2015 in Tapoa Province, in the Eastern Region of Burkina Faso. The aim 72 was to evaluate whether multiannual seasonal unconditional cash transfers helped prevent 73 acute malnutrition in young children. It was designed as a cluster randomized controlled trial, 74 in which 16 villages received monthly cash payments from July to November in both 2013 75 and 2014, and 16 other villages were used as the control group. The cash (10,000 76 FCFA/month, approx. US\$17) was distributed to mothers via mobile phone, with no 77 conditions or restrictions on use. As cash transfers were unconditional, beneficiaries didn't 78 have to fulfill conditions other than the inclusion criteria in order to receive cash. In June 79 2013, 1,278 children under 1 year of age and living in poor or very poor households according to the Household Economy Approach [18] were included in the study and followed 80 up for up to two years. The study, including the 24-h dietary recall survey, was registered in 81

ClinicalTrials.gov (NCT01866124) on May 7, 2013, and received ethical approval from two
separate ethics committees: in April 2013 from the Ethical Committee of the University
Hospital of Gent and in May 2013 from the Burkinabe National Ethical Committee.

85 Study population and sample size

86 The Eastern Region of Burkina Faso has a Sudan-Sahelian climate, characterized by two 87 distinct seasons: a hot and dry period from October to May and a rainy season from June to September. The 24-h dietary recall was a cross-sectional sub-study nested within the 88 89 MAM'Out study. Due to limited access in the rainy season, six remote clusters were 90 purposely excluded from this sub-study: three in the control group and three in the 91 intervention group. A subsample of children included in the MAM'Out study was then randomly chosen among the 26 remaining villages to be part of the 24-h dietary recall study. 92 93 No restriction was put on the children's age or nutritional status. Children in both arms were 94 randomly selected using the computer random number generator in Stata 12.0 (Statacorp, 95 USA). With a Type I error of 5% and a statistical power of 80%, assuming a size effect of 0.4 and a design effect of 1.5 [19], with 13 clusters per study arms, 156 children per study arm 96 were required. Allowing for 5-10% non-response we increased the sample size to 166 per 97 98 study arm.

99 Data collection

100 Four teams of two data collectors received one week of training on the multi-pass 24-h 101 dietary recall method [20]. Standardization exercises for food weight measurements and 102 interview techniques were taught and questionnaires pre-tested. All data collectors spoke 103 Gulmancema (the main local language) and two also spoke Pulaar fluently. Two of the data 104 collectors were selected to be supervisors during data collection to check the quality of data collection and coordinate awareness raising activities on the 24-h dietary recall study. These 105 activities took place one or two days prior to data collection and consisted in a visit to the 106 107 selected household and the presentation of the data collection procedure. The caregiver was also given a standard 24-h recall kit comprising a plate and a bowl to estimate the quantities
eaten by the child. Caregivers were asked to set aside a small quantity of the food eaten by
the child the day before the visit to facilitate the recall and to take note of the ingredients
used to prepare the food.

Data were collected during the lean season and the cash transfer period (July and August 112 113 2014). It consisted of two interactive 24-h dietary recalls and two questionnaires on breastfeeding practices per child on two non-consecutive days. This was meant to reduce 114 bias due to dependency of intake on two consecutive days due to the possible consumption 115 of leftovers. On the day of data collection, data collectors asked the caregiver to describe the 116 117 food consumed by the child on the previous day. Information was recorded on a classic 24hour food recall form as proposed by Gibson and Ferguson [20]. To minimize recall bias, 118 119 interviews were held using a standardized three pass method adapted from Gibson and Ferguson's manual for developing countries [20]. First, the caregiver was asked to recall all 120 121 the foods the child ate the previous day, including snacks and drinks, from the moment the 122 caregiver woke up the day before until the moment they woke up on the day of the recall 123 interview. The caregivers were then asked to describe the composition of the enlisted 124 composite foods and beverages. The next step was estimating the amounts of foods and 125 beverages consumed using the recall kit. Tanita digital scales, model KD-400 (Tanita Corporation, USA) (precision 1 g) were used to weigh the food. The scales were calibrated 126 daily. In the final step, the data collectors read back all the answers to check no answers had 127 been omitted. Each interview lasted between 45 minutes and one hour. 128

Recalled composite food and beverage intakes were converted to single ingredients using standardized recipes. A list of the main composite dishes was then extracted from preliminary analysis of the 24-h dietary recall data. For each composite dish, five caregivers living in the study area were asked to prepare the composite food to identify its main ingredients. Raw ingredients, their amounts, the total cooked weight and volume were recorded to compile standardized recipes.

As the children randomly selected to participate in the 24-h dietary recall surveys were 135 between 14 and 27 months old, many of them were still breastfed. Hence breastfeeding 136 137 practices were evaluated in addition to the quantity of food eaten using a detailed 138 questionnaire. The number of times a child was breastfed, the time of the day and the approximate duration of each session were recalled. Data collectors asked the caregiver to 139 recall their previous day, beginning when they woke up the previous day and ending when 140 141 they woke up on the day of the interview. Each breastfeed was then recorded in a table with 142 its approximate duration (0-10 minutes, 11-20 minutes or 21-30 minutes).

The data collected in the 24-h dietary recalls and breastfeeding questionnaires were coded with the unique identification number allocated to each child in the MAM'Out study [17]. None of the paper records included the child's name or address.

146 In addition, data concerning the children's nutritional status and date of birth, level of 147 education of the caregiver and the households' socio-economic status (SES) were imported from the MAM'Out database for the purpose of analysis. For SES, tertiles were created 148 among the poor and very poor households included in the study using principal component 149 analysis (PCA) based on declared assets ownership. Stunting is defined by a height-for-age 150 151 Z-score inferior to -2 (according to the 2006 WHO growth standards [21]) and wasting as a weight-for-height Z-score inferior to -2 or presence of bilateral pitting edema. These data 152 153 were collected from June 23 to September 26, 2014, thus including the 24-h dietary recall 154 period.

155 Data analyses

Data on the 24-h dietary recalls were entered in Lucille®, a computer program conceived by Ghent University, Belgium, and analyzed using Stata 12.0. The food composition table used to describe the quality of the intake was a combination of three sources. The West African food composition table endorsed and developed by the Food and Agriculture Organization and the International Network of Food Data System [22] was used as the primary data

source to obtain energy and nutrient concentrations per food. However, a check of the 24-h 161 162 dietary recall questionnaires revealed that some food products consumed by the children were missing. Information on the missing products was taken from the food composition 163 164 table for Burkina Faso also used by Arsenault and al. [19]. If no information was available on a given food (e.g. sparrow hawk meat and djonkin juice) in the Burkinabe table, an Internet 165 search was conducted or the information (for Yonhanma flour, Plumpy'nut and 166 Supplementary Plumpy) was taken from the label on the food product. The composition of 167 168 73% of the ingredients of the consumed food were obtained from the West African food composition table [22], 20% from the Burkina Faso food composition table [19], 3% from 169 170 Internet and 4% from food product labels.

171 The absorption of certain micronutrients such as iron, calcium and zinc by the human body 172 depends on their chemical forms and on the presence of anti-nutrients that inhibit absorption 173 [20]. To account for differences related to the different food sources, absorbed iron was 174 calculated based on the bioavailability factors of iron and 6% of iron bioavailability was 175 applied to plant food sources and 11% to animal ones [23, 24]. For absorbed calcium, 25% 176 was applied to roots, tubers, legumes and grains, 45% to fruits and vegetables, 32% to all 177 other food groups [24]. As phytate concentrations were not available, it was not possible to calculate the phytate to zinc molar ratio. The absorption level for zinc derived from the 2004 178 working group of the International Zinc Nutrition Consultative Group was used instead. The 179 15% zinc bioavailability is based on a diet based on unrefined cereals [25]. 180

Data obtained from the breastfeeding questionnaires were entered in Epidata software and analyzed using Stata 12.0. The mean duration of breastfeeding was calculated by summing the approximate durations of each breastfeeding session over the recalled day: 5 minutes was used if the mother said breastfeeding lasted between 1 and 10 minutes, 15 minutes if the answer was between 11 and 20 minutes, and 25 minutes if the answer was 21-30 minutes. The mean number of breastfeeding sessions, the mean duration of a breastfeeding session and the percentage of children still breastfed were also calculated.

A dietary diversity score (DDS) was calculated based on seven food groups, namely (1) 188 189 Grains, roots and tubers; (2) Legumes and nuts; (3) Dairy products; (4) Flesh food; (5) Eggs; 190 (6) Vitamin A rich fruits and vegetables; (7) Other fruits and vegetables [26]. DDS were 191 calculated by summing the number of unique food groups eaten by the child during the 24h dietary recall period. Meal frequency was calculated by summing the number of time each a 192 193 child ate solid, semi-solid or soft foods (even a snack), during the day. The minimum 194 acceptable diet was defined by the World Health Organization as having a DDS equal to or 195 above 4 and a sufficient meal frequency (e.g. 3 and 4 meals/24 h for breastfed and nonbreastfed children, respectively) [26]. The proportion of children consuming iron-rich or iron-196 197 fortified food was also calculated including the consumption of flesh food and commercial or homemade fortified foods. 198

199 The 2005 estimated energy requirement (EER) by age group and sex published by the 200 Institute of Medicine [27] were used to identify outliers for energy intakes. An arbitrary over-201 reporting threshold was established when the mean energy intake of a child was more than 202 twice the EER for his/her sex and age group. In the same way, underreporting was 203 considered when the mean energy intake was less than 30% of the EER for the child's age 204 group and sex. A total of eight children were excluded from the study: three for over-reporting 205 in the control group, four for over-reporting in the cash group and one for under-reporting in 206 the control group. Two children aged more than 27 months old were also excluded from the 207 study because they were outliers in age. Data were analyzed with and without exclusion of 208 these 10 children and the overall results did not differ.

The primary outcome of the study was child energy intake. Usual intake distributions of nutrients and energy were generated using the Multiple Source Method (MSM) [28] based on the two dietary recalls collected per child. No covariate was added to the model. The usual intake distributions obtained were subsequently used to calculate means and standard deviations to describe the children's intakes. Differences in energy and nutrient intakes between the intervention and the control groups were analyzed using linear mixed models

including village as random effect to account for clustered observations. Fixed effects 215 included in the models were the child's age at recall, child's sex, mother's literacy rate and 216 217 household's socio-economic status. When the distribution was not bell shaped, variables 218 were first log-transformed and then analyzed. Mixed-effects Poisson regression models were 219 used to analyze differences in the dietary diversity score and the number of meals per day. Random and fixed effects were the same as the ones described above. Differences in the 220 221 quantities of each food group consumed by children in the intervention and control groups 222 were analyzed using a gamma generalized linear model (GLM) with log link [29] adjusted for village as random effect and adjusted for all the above mentioned co-variates. This model 223 224 was chosen to take into account the high frequencies of non-consumption among the data, 225 resulting in many zeros in the dataset. All the tests were two-sided and a statistical 226 significance level of 5% was used for all analyses.

227

228 **Results**

229 General characteristics

230 The data available for analysis included two dietary recalls from 322 children aged 14 to 27 231 months (figure 1). All children sampled were surveyed. The child characteristics (table 1) were balanced between children in the intervention and control group for age and 232 233 breastfeeding practices. Children were on average 20.5 ± 0.16 months old and 72% were still partially breastfed. The mean duration of breastfeeding per day was 52.3 ± 2.18 minutes and 234 each breastfeeding session lasted 6.86 ± 0.28 minutes. The intra-class correlation between 235 the two recalls for the duration of each breastfeeding session was 0.80 (95% CI: 0.76, 0.84) 236 (p<0.0001), for the total duration of breastfeeding per day 0.80 (95% CI: 0.76, 0.84) 237 238 (p<0.0001) and for the mean number of breastfeeding session per day 0.56 (95% CI: 0.48, 0.65) (p<0.0001). Child nutritional status was also balanced between the intervention and 239 240 control group with the exception of the mean weight-for-height Z-score, which was slightly

lower in the control group than in the intervention group (-0.89 \pm 0.07 vs. -0.77 \pm 0.07). The socio-economic status also slightly differed between households benefiting from cash transfers and control households, with more intervention households being classified as having a medium socio-economic status (40.9 % vs 32.9 %).

245 Indicators for food diversity and infant and young child feeding practices

After the cash transfer, the 24-h dietary recall surveys identified that a bigger proportion of children in the intervention group ate milk and dairy products (25.0 % vs 7.41%; p=0.007), flesh food (26.3% vs 14.8%; p=0.01) and eggs (31.3% vs 11.1%; p=0.003) compared to children in the control group (**Table 2**). In terms of quantities, children in the intervention group ate on average more eggs (p<0.001) than children in the control group (**Table 3**).

251 There was a trend towards a higher mean diet diversity score for the children in the 252 intervention group (4.02 ± 0.06) compared to that of the children in the control group (3.61 ± 1.06) 253 0.05) (p=0.07) (**Table 4**). Approximately two thirds of the children in the intervention group had adequate minimum dietary diversity compared with one third in the control group 254 (p<0.001). We did not observe a difference in the frequency of meals between the groups 255 and almost all children in both groups had an adequate minimum meal frequency. The 256 percentage of children who consumed iron-rich or iron-fortified food was also higher in the 257 intervention group (35.6%) than in the control group (21.1%) (p<0.05). 258

259 Energy and nutrient intakes

We didn't find any significant difference in mean energy intake from complementary food (defined as all solid, semi-solid and soft foods given to the children in addition to breastfeeding) between the intervention and the control groups (**Table 5**). However, we measured that children in the intervention group ate more fat (p<0.01) than children in the control group and had a tendency of consuming more protein (p=0.06). Considering the contribution of macronutrients to energy intake, children who benefited from cash transfers consumed more energy from fats (p<0.01) and less from carbohydrates (p<0.01) than
children in the control group.

Children in the intervention group had a statistically significant higher vitamin B12 (p<0.001), riboflavin (p<0.05) and vitamin E (p<0.05) intake than children in the control group (**Table 6**).

270

271 **Discussion**

Our study aimed to assess the effects of seasonal unconditional cash transfers on energy, micro- and macronutrient intake of young Burkinabe children using the strong design of a randomized controlled trial. The results of the 24-h dietary recall surveys showed that cash transfer during the lean season improved the diet of 14 to 27-month old children. We observed positive effects on the quantity of eggs consumed as well as on the percentage of children consuming meat, eggs and dairy products.

278 Our results of the impact of an unconditional cash transfer on children's dietary diversity and 279 frequency of food group consumption are in line with those of two other studies that 280 investigated the effect of unconditional cash transfers on children's diet. The Malawi Social Cash Transfer Scheme led to a more diverse diet in beneficiary households with more 281 282 people eating meat, fish and dairy products compared to households in the control group [15]. In Kenya, Haushofer and al. found that households benefiting from unconditional cash 283 transfers ate meat and fish more frequently than households in the control group [30]. 284 285 Approximately two thirds of the children in the intervention group benefited from adequate 286 minimum dietary diversity compared to only one third in the control group. This is a significant improvement over the figures cited in the most recent demographic and health 287 survey conducted in Burkina Faso, which reported that only 6.2% of children aged 6-23 288 289 months living in the Eastern Region consumed at least four food groups [31]. It is however noteworthy to mention that 13.4% of the children in our study are 24 months old or above, 290 291 and that we surveyed children from 2 municipalities out of 27 of the Eastern Region.

13

We did not observe a difference in mean energy intake between children in the intervention group and in the control group. However, the source of energy differed between the two groups: energy originated mainly from fat in children in the intervention group and to a lesser extent from carbohydrates as compared to children in the control group. Nevertheless, relative fat intake remained to the lower end of the recommended complementary food fat intake values (between 21% to 43% of the energy intake in case of medium level of energy intake from breastmilk [32]).

299 Children in the present study had a mean complementary food density of 0.77 kcal/g and ate an average of 4.8 meals per day. According to Dewey and Brown [32] children aged 12 to 23 300 301 months with a low level of energy intake from breastmilk should eat a minimum of 5 meals per day if the complementary food density is 0.6 kcal/g, and 3.7 meals per day if the density 302 303 reaches 0.8 kcal/g. This number is based on the definition of meal frequency including both meals and snacks, as defined by the World Health Organization [26]. Therefore, our results 304 305 show that the complementary food density was adequate during the lean season and 306 corresponded to international recommendations. This result was quite unexpected during the 307 lean season, given the high carbohydrate and low fat content of the complementary food the 308 children received. This outcome is partly due to the number of meals or snacks each child 309 consumed each day. In our study, the meal frequency of 99% of all children was adequate, 310 compared to that of only 39% of all children aged 6-23 months and living in the Eastern 311 Region of Burkina Faso [31]. One possible explanation could be linked to the age of the children we surveyed, who are in average 20.5 months old, with 13% of the children above 312 24 months old. 313

Vitamin B12, riboflavin and vitamin E intakes were significantly higher in children in the intervention group. This is encouraging given the important role of vitamins B12 and E in immune system [33]. The higher intake of vitamin B12 may be the consequence of the larger quantity of eggs eaten by children in the intervention group. However, despite the larger quantities of iron-rich food consumed, we found no difference in iron intake between the twogroups.

320 Several strengths can be highlighted for this study. The 24-h dietary recalls were 321 implemented in the framework of a cluster randomized controlled trial and took advantage of its strong design. All the basic characteristics of the intervention and control groups, including 322 323 height-for-height Z-score, were comparable, except for the slightly lower mean weight-forheight Z-score of children in the control group. However, as adjusting the analyses for the 324 nutritional status and breastfeeding practices, which may both have changed as a result of 325 the cash transfer program, holds a risk of bias, we did not adjust the analyses for these two 326 327 factors. The one week training the data collectors underwent on the 24-h food recall methodology allowed for the standardization and pretesting of the method of data collection. 328 329 In addition, the two month period of data collection was supervised: every week, two of the 330 children visited by each data collector were visited a second time by the supervisor to check 331 on the data collected. A number of study limitations also need to be addressed. First, we 332 were unable to adjust analyses for data collectors, due to an error during data entry. 333 Collector bias was nevertheless limited by the fact that two different data collectors systematically conducted the two recalls in the same household. Secondly, the six clusters 334 335 excluded from data collection due to difficult access may have had higher prevalence of acute malnutrition, compared to those included. The effect of the intervention might also 336 have been lower in these villages due to limited access to market. Thirdly, two thirds of the 337 children in the study were still breastfed at the time of the evaluation. To our knowledge, no 338 339 precise technique to evaluate the quantity of milk consumed by children is currently available beyond weighing the baby before and after breastfeeding or giving isotopic labeled water to 340 341 mothers. In the MAM'Out study area, it was not possible to use either of these techniques due to operational constraints. We tried to overcome this problem by designing a detailed 342 343 questionnaire on breastfeeding practices to estimate the number of times a child was 344 breastfed during the day and the corresponding duration, but this was still not sufficient to

estimate energy intake from breastmilk. One possible solution would have been to 345 346 hypothesize average breast milk intake as has been done in previous studies [34]. However, 347 this is still an estimation and does not measure the breastmilk intake precisely. Since the 348 same estimation method was used in both groups, we assume that the measurement error 349 was similar for the two groups. Fourthly, we did not adjust our analyses for multiple hypothesis testing. Although this is still an ongoing debate [35], concerns may be raised 350 about the need to reevaluate the p-value used for the significance of results, which may 351 352 decrease the number of significant differences we found between groups. However, the results presented here tend to go in the same direction (with higher number of children 353 354 consuming animal products in the intervention group, more eggs intake in term of quantities 355 and more B12 intake), which strengthen confidence in them [35]. Finally, no measurement of 356 body composition or biomarkers before and after the intervention was performed. As such, it 357 is hard to see the direct health benefits of the intervention. However, our results demonstrate first of all that unrestricted and unconditional cash was used for food purposes and allow 358 359 improving children's diet quality. Yet, the amount distributed may have been too low with 360 respect to the family size in order to have a positive effect on child's health via an improved diet quality. 361

362

363 **Conclusion**

Unconditional cash transfers during the lean season did not lead to a higher energy intake, 364 but improved the intake of mainly animal source foods amongst 14 to 27-month old 365 366 Burkinabe children living in rural areas. Two thirds of the children who benefited from cash transfers also had an adequate minimum dietary diversity score compared to only one third 367 in the control group. Our results support the implementation of unconditional seasonal cash 368 369 transfer programs to improve children's diet and nutritional intake during the lean season. We 370 therefore recommend their use in actions addressing children's dietary intake during this 371 difficult period.

Tables

Table 1: General characteristics of Burkinabe children of 14 - 27 months of age

	Control	Intervention
	(n=162)	(n=160)
Clusters, n	13	13
Children's age, mo	20.6 ± 0.22	20.4 ± 0.23
Male children, n (%)	79 (48.8)	91 (56.9)
Children still breastfed, %	74.1	70.6
Breastfeeding sessions, n /d	7.88 ± 0.15	7.73 ± 0.18
Duration of one breastfeed session, min	7.14 ± 0.30	6.32 ± 0.29
Total duration of breastfeeding, min/d	55.8 ± 3.05	48.7 ± 3.10
Child weight-for-height z-score ^a	-0.89 ± 0.07	-0.77 ± 0.07
Child height-for-age z-score ^a	-1.96 ± 0.09	-1.97 ± 0.08
Wasted children, % ^a	9.88	8.23
Stunted children, % ^a	46.9	48.7
Literate mothers, % ^c	24.7	20.1
Households socio-economic status: low /	35.4 / 32.9 / 31.7	30.8 / 40.9 / 28.3
medium / high, % ^b		

Values presented in this table are means $(\pm SD$ when applicable) and percentages.

^a Nutritional status data were available for 162 children in the control group and for 158 in the intervention group

^b Socio-economic data were available for 161 children in the control group and 159 in the intervention group. Tertiles were created among the poor and very poor households included in the study using principal component analysis (PCA) based on declared assets ownership.

^c Education data were available for 162 children in the control group and 159 in the intervention group

Table 2: Proportions of 14-27 months old Burkinabe children consuming each of the sevenfood groups during the last 24 hours

	Control arm	Intervention arm	Odd ratios	P-value
			(95% CI) ^d	
Grains, roots	100 ± 0.00	99.4 ± 0.63	NA	NA
and tubers (%)				
Legumes and	66.0 ± 3.73	72.5 ± 3.54	1.40 (0.57, 3.43)	0.47
nuts (%)				
Milk and dairy	7.41 ± 2.06	25.0 ± 3.43	4.14 (1.48, 11.6)	0.007
products (not				
including				
breastfeeding)				
(%)				
Flesh food	14.8 ± 2.80	26.3 ± 3.49	2.09 (1.18, 3.70)	0.01
(meat, fish,				
poultry) (%)				
Eggs (%)	11.1 ± 2.48	31.3 ± 3.68	3.61 (1.56, 8.37)	0.003
Vitamin A rich	98.8 ± 0.87	96.3 ± 1.51	0.36 (0.07, 1.83)	0.22
fruits and				
vegetables (%)				
Other fruits and	1.23 ± 0.87	2.50 ± 1.24	2.32 (0.38, 14.1)	0.36
vegetables (%)				

Values presented in this table are proportions (± SD).

^d Analyzed using a mixed logistic regression model with *village* as random effect and adjusted for child's sex, age, household's SES and mother's literacy rate

	Control arm	Intervention arm	P-value ^e
Grains, roots and	158.6 ± 5.26	163.5 ± 5.53	0.49
tubers (g/d)			
Legumes and nuts	12.6 ± 1.37	14.7 ± 1.35	0.28
(g/d)			
Milk and dairy	18.7 ± 7.49	46.3 ± 9.37	0.33
products (not			
including			
breastfeeding)			
(g/d)			
Flesh food (meat,	2.02 ± 0.54	4.00 ± 0.79	0.12
fish, poultry) (g/d)			
Eggs (g/d)	3.25 ± 0.79	11.3 ± 1.55	<0.001
Vitamin A rich	38.4 ± 2.68	33.6 ± 2.17	0.29
fruits and			
vegetables (g/d)			
Other fruits and	0.44 ± 0.42	0.33 ± 0.25	NA ^f
vegetables (g/d)			

Table 3: Mean daily intake of seven food groups of 14-27 months old Burkinabe children

Values presented in this table are means (± SD).

^e Analyzed using a gamma generalized linear model with log link, with *village* as random effect and

adjusted for child's sex, age, household's SES and mother literacy rate

^f Non Applicable. Only 6 consumers in total

Table 4: Infants' and young children's feeding indicators for 14-27 months old Burkinabe children

	Control arm	Intervention	Odds ratio (95% CI)	P-value
		arm		
Dietary diversity score (7 food	3.61 ± 0.05	4.01 ± 0.06	NA	0.07
groups) ^g				
Children with adequate	64 (39.5)	105 (65.6)	2.95 (1.86, 4.68)	<0.001
minimum dietary diversity, n				
(%) ^h				
Mean number of meals / day	4.76 ± 0.06	4.92 ± 0.06	NA	0.66
for breastfed children ^g				
Mean number of meals / day	4.72 ± 0.10	4.95 ± 0.09	NA	0.65
for non-breastfed children ^g				
Children with adequate	160 (98.8)	159 (99.4)	1.72 (0.12, 25.5)	0.69
minimum meal frequency, n				
(%) ^h				
Children with minimum	64 (39.5)	105 (65.6)	2.95 (1.86, 4.68)	<0.001
acceptable diet, n (%) ^h				
Children consuming iron rich	33 (20.4)	58 (36.3)	2.23 (1.20, 4.13)	0.01
or iron fortified food, n (%) ^h				

Values presented in this table are means (± SD) or number of children (and the

corresponding percentages).

⁹ Analyzed using a mixed Poisson regression model with *village* as random effect and adjusted for child's sex, age, household's SES and mother's literacy rate

^h Analyzed using a mixed logistic model with *village* as random effect and adjusted for child's sex, age,

household's SES and mother's literacy rate

Table 5: Energy and macronutrient intake from complementary foods of 14-27 months oldBurkinabe children

	Control Arm	Intervention	P-value
		Arm	
Energy (kcal / day) ⁱ	915 ± 24.1	962 ± 23.6	0.20
Energy (kJ / day) ⁱ	3828 ± 101.0	4026 ± 98.7	0.20
Complementary food energy	0.78 ± 0.15	0.79 ± 0.14	0.57
density (kcal/g) ⁱ			
Fat (g/day) ⁱ	16.5 ± 0.89	20.6 ± 0.80	0.001
Carbohydrates (g/day) ⁱ	169 ± 4.33	169 ± 5.01	0.59
Protein (g/day) ⁱ	20.1 ± 0.60	21.7 ± 0.55	0.06
Fiber (g/day) ⁱ	13.5 ± 0.45	12.2 ± 0.39	0.10
Fat (% of total energy) ⁱ	15.7 ± 0.60	19.7 ± 0.71	0.004
Carbohydrates (% of total	74.5 ± 0.72	69.8 ± 0.89	0.006
energy) ^j			
Protein (% of total energy) ⁱ	8.87 ± 0.16	9.29 ± 0.23	0.34

Values presented in this table are means (± SD).

ⁱ Analyzed using a mixed linear model (after log transformation) with *village* as random effect and

adjusted for child's sex, age, household's SES and mother's literacy rate

^j Analyzed using a mixed linear model with *village* as random effect and adjusted for child's sex, age,

household's SES and mother's literacy rate

Table 6: Micronutrient intake from complementary foods of 14-27 months old Burkinabe children

	Control arm	Intervention arm	P-value ^k
Minerals			
Ca (mg/d)	248.7 ± 10.9	263.0 ± 9.60	0.31
Available Ca (mg/d)	86.8 ± 3.26	89.6 ± 2.83	0.45
Fe (mg/d)	19.7 ± 0.79	19.4 ± 0.64	0.79
Available Fe (mg/d)	0.47 ± 0.02	0.52 ± 0.02	0.46
Mg (mg/d)	165.9 ± 5.86	153.5 ± 4.90	0.28
Zn (mg/d)	4.31 ± 0.16	4.51 ± 0.15	0.33
Available Zn (mg/d)	0.65 ± 0.02	0.68 ± 0.02	0.33
Vitamins			
Vitamin A (µg/d)	96.3 ± 5.55	111.7 ± 5.51	0.13
Vitamin C (mg/d)	219.4 ± 8.75	215.2 ± 11.3	0.23
Vitamin E (mg/d)	4.50 ± 0.33	5.55 ± 0.31	0.01
Thiamin B1 (mg/d)	0.34 ± 0.01	0.36 ± 0.01	0.25
Riboflavin (mg/d)	0.34 ± 0.02	0.40 ± 0.02	0.04
Nicotinic acid (mg/d)	3.38 ± 0.10	3.31 ± 0.10	0.82
Vitamin B6 (mg/d)	0.42 ± 0.01	0.40 ± 0.01	0.74
Folic acid (µg/d)	60.7 ± 2.18	66.4 ± 2.17	0.19
Vitamin B12 (µg/d)	0.21 ± 0.04	0.52 ± 0.06	<0.001

Values presented in this table are means (± SD).

^k Analyzed using a mixed linear model (after log transformation) with *village* as random effect and adjusted for child's sex, age, household's SES and mother's literacy rate
